

This could be any other module---e.g., material, building, transportation, etc.

** It is assumed that impacts of the model happen at the item level and the total impact is the sum of those impacts.*

*MCS should be able to work with any module. This will have a list of **'items'** (object types) and check if those (attributes of those type) in the model have **distributions**. The distribution will specify which **parameter** of the item it is varying. For each item (regardless of having distributions) it will operate the **get_impacts method** and sum all impacts. Those items without a distribution will have a probability of 1.*

The user will assign the data set.

If there are default data sets, it might worth having a Database Manager. Otherwise, the option to load data from different sources is suffice.
